

Using Neutron Scattering and Quantum Theory to Tune Catalyst Selectivity and Optimise Bioactive Composites

Prof. Gregory Chass, Queen Mary, University of London

Librational and low-energy vibrational (i.e. far-infrared) phenomena have long been associated with functional properties of material and molecular systems. However, accessing this ‘fingerprint’ region by standard spectroscopic methods is hindered by selection rules, sensitivity and energy resolution. Neutron scattering methods provide a solution, with associated phenomena now spatially, energetically and temporally intelligible in conjunction with quantum theory.

Employing a ‘Systems’ approach and quantum theory, we designed and carried out a series of inelastic neutron experiments at the ISIS pulsed neutron and muon facility at the Rutherford Appleton Laboratory (RAL, Oxfordshire, UK). The TOSCA indirect-geometry experimental setup was used to characterise low energy dynamics of cross-coupling catalysts employed in the production of functional materials. A widely-used bioactive composite was likewise analysed towards understanding changes in material properties during setting on the VESUVIO neutron compton scattering experiment.

TOSCA results showed catalyst performance to be a function of cooperative dynamics. Quantification of each molecular component’s contribution to the overall systemic properties of 3 cross-coupling catalyst families revealed low-energy vibrational modes (terahertz) to be intimately coupled to reaction pathway preference in each family.

Results derived on VESUVIO allowed for quantitative tracking in real-time of kinetic energy for each atom in the composite cement. Atom-specific bonding strengths were subsequently derived and tracked over the course of the setting reaction, showing the polymer component’s C-C and C-O bonds as the major contributors ‘providing toughness’ to the composite bulk.

The talk provides an overview of neutron spectroscopy, touching on the evolution and successful application of quantum theory in the design of effective neutron beam experiments for the two project areas: 1) selectivity and reactivity in catalysed functional material production; 2) rational elevation of material toughness in bioactive composites.
